

Grammarly for your privacy

Stop leaking secrets into ChatGPT & the web — 100% on-device.

The problem

People paste sensitive data — passwords, credit cards, Aadhaar/PAN, API keys — into AI chatbots and websites every day, often without realising it. Once it's sent, it's out of their control. Companies are scrambling for “DLP for AI” (data-loss prevention for tools like ChatGPT); individuals have almost nothing.

The solution

North Star is a Chrome extension that watches every text field and warns you the instant you type or paste something sensitive — like a spell-checker, but for privacy. It underlines the risky text inline, lists exactly what it caught, and lets you redact it in one click, all **before you hit send**. Every check runs locally in the browser, so a privacy tool never becomes a privacy risk.

Why it stands out

100% local	No server, no account, no tracking — text never leaves the device.
Real-time	Grammarly-style inline warnings as you type, in any field incl. AI chatbots.
Broad + accurate	28+ data types with Luhn/Verhoeff checksums to cut false alarms.
Compliance-ready	Optional dashboard maps findings to GDPR & India DPDP; PDF audit reports.

Market & model

Open-core. The personal extension is free and open-source to drive adoption. A paid **Teams** tier targets companies worried about staff leaking data into AI tools — adding org-wide policy, the audit dashboard, and compliance reporting. The consumer product is the wedge; oversight is the revenue.

Built with

Extension: Manifest V3, vanilla JS detection engine (shared across content script, popup, background).

Platform: FastAPI · PostgreSQL · Redis · React + TypeScript · Docker · GitHub Actions CI (33 tests).

Engineering highlights: overlay-based inline highlighting inside non-editable fields; deterministic, reproducible risk scoring; privacy-by-design (no raw PII persisted).
